

Intergenerational Altruism, Fertility, and Welfare Across Countries and Time

Preliminary and Incomplete

Anson Zhou

October 4, 2021

Motivation

- A good welfare measure is important for understanding:
 - Inequality: differences in living standard across countries
 - Growth: evolution of living standard over time

Motivation

- A good welfare measure is important for understanding:
 - Inequality: differences in living standard across countries
 - Growth: evolution of living standard over time
- GDPPC is an imperfect measure of welfare (Fleurbaey 2009)
- Existing work (Becker et al. 2005; Jones and Klenow 2016) focus on consumption, leisure, **life expectancy**, and inequality

This Paper

- This paper incorporates **intergenerational altruism** into welfare analysis

This Paper

- This paper incorporates **intergenerational altruism** into welfare analysis
- Why intergenerational altruism?
 1. Crucial in explaining fertility and parents' spending on children
 2. Reveal constraints not shown in traditional measures

This Paper

- This paper incorporates **intergenerational altruism** into welfare analysis
- Why intergenerational altruism?
 1. Crucial in explaining fertility and parents' spending on children
 2. Reveal constraints not shown in traditional measures
- As the degree of altruism increases in fertility (Barro and Becker 1989), large gaps in fertility \implies large variations in utility derived from altruism

The Model

- Jones and Klenow (2016):

$$\underbrace{U_i}_{\text{country } i\text{'s lifetime utility}} = \underbrace{e_i}_{\text{life expectancy}} \cdot \underbrace{u(\underbrace{c_i}_{\text{consumption}}, \underbrace{l_i}_{\text{leisure}}, \underbrace{\sigma_i}_{\text{inequality}})}_{\text{flow utility}}$$

The Model

- Jones and Klenow (2016):

$$\underbrace{U_i}_{\text{country } i\text{'s lifetime utility}} = \underbrace{e_i}_{\text{life expectancy}} \cdot \underbrace{u(\underbrace{c_i}_{\text{consumption}}, \underbrace{l_i}_{\text{leisure}}, \underbrace{\sigma_i}_{\text{inequality}})}_{\text{flow utility}}$$

- Barro and Becker (1989):

$$\underbrace{V_i}_{\text{parents' welfare}} = \underbrace{U_i}_{\text{parents' utility}} + \underbrace{\Psi(\underbrace{n_i}_{\text{fertility}})}_{\text{degree of altruism}} \cdot \underbrace{U'_i}_{\text{child's utility}}$$

The Model

- Jones and Klenow (2016):

$$\underbrace{U_i}_{\text{country } i\text{'s lifetime utility}} = \underbrace{e_i}_{\text{life expectancy}} \cdot \underbrace{u(\underbrace{c_i}_{\text{consumption}}, \underbrace{l_i}_{\text{leisure}}, \underbrace{\sigma_i}_{\text{inequality}})}_{\text{flow utility}}$$

- Barro and Becker (1989):

$$\underbrace{V_i}_{\text{parents' welfare}} = \underbrace{U_i}_{\text{parents' utility}} + \underbrace{\Psi(n_i)}_{\substack{\text{fertility} \\ \text{degree of altruism}}} \cdot \underbrace{U'_i}_{\text{child's utility}}$$

- When parents expect $U'_i = U_i$,

$$V_i = \underbrace{\frac{1}{1 - \Psi(n_i)}}_{\text{altruism-adjusted life expectancy } (\tilde{e})} \cdot e_i \cdot \underbrace{u(c_i, l_i)}_{\text{flow utility}} \quad (1)$$

Welfare Measure: Consumption Equivalence

- Denote factor λ as:

$$V_i(\lambda) = U_i(\lambda) + \Psi(n) \cdot \mathbb{E}U'_i(\lambda)$$

where $U_i(\lambda) = e_i \cdot u(\lambda \cdot c_i, l_i, \sigma_i)$

Welfare Measure: Consumption Equivalence

- Denote factor λ as:

$$V_i(\lambda) = U_i(\lambda) + \Psi(n) \cdot \mathbb{E}U'_i(\lambda)$$

$$\text{where} \quad U_i(\lambda) = e_i \cdot u(\lambda \cdot c_i, l_i, \sigma_i)$$

- The consumption equivalent λ_i for country i solves:

$$V_i(1) = V_{\text{U.S.}}(\lambda_i)$$

Rawls is indifferent between living in country i and living in the U.S. with consumption scaled by λ_i

Decomposition

- Decomposition of welfare differences across countries / over time:

$$\begin{aligned}
 \log(\lambda_i) &= \frac{\tilde{e}_t}{\tilde{e}_{\text{U.S.}}} \cdot \left(\bar{u} + \log C_i + v(l_i) - \frac{1}{2} \cdot \sigma_i^2 \right) - \left(\bar{u} + \log C_{\text{U.S.}} + v(l_{\text{U.S.}}) - \frac{1}{2} \cdot \sigma_{\text{U.S.}}^2 \right) \\
 &\stackrel{\text{decompose}}{=} \underbrace{\log(Y_i) - \log(Y_{\text{U.S.}})}_{\text{GDP per capita}} + \underbrace{\log(C_i/Y_i) - \log(C_{\text{U.S.}}/Y_{\text{U.S.}})}_{\text{consumption share}} \\
 &\quad + \underbrace{v(l_i) - v(l_{\text{U.S.}})}_{\text{leisure}} + \underbrace{\frac{1}{2} \cdot (\sigma_{\text{U}}^2 - \sigma_{it}^2)}_{\text{inequality}} \\
 &\quad + \underbrace{\frac{\tilde{e}_i - \tilde{e}_{\text{U.S.}}}{\tilde{e}_{\text{U.S.}}} \cdot \left(\bar{u} + \log C_i + v(l_i) - \frac{1}{2} \cdot \sigma_i^2 \right)}_{\text{altruism-adjusted life expectancy}}
 \end{aligned} \tag{2}$$

- Key difference from Jones and Klenow (2016): \tilde{e}_i rather than e_i in the life expectancy (LE) term

Result 1: Welfare Across Countries in 2007

- Upward (downward) adjustment when total fertility rate is high (lower) than the U.S.
- Welfare of many countries are adjusted downward, and such adjustments are usually sizable because $\Psi(n)$ is concave

Result 1: Welfare of OECD Countries in 2007

- Welfare of 19 countries are adjusted upward in Jones and Klenow (2016) due to higher life expectancy, but are adjusted downward with intergenerational altruism
- Example: Japan vs United States:

$$e_{\text{Japan}} = 82.5 > e_{\text{U.S.}} = 77.8$$

$$n_{\text{Japan}} = 1.34 < n_{\text{U.S.}} = 2.05$$

$$LE_{\text{Japan}} = 0.24 \gg -0.16 = \widetilde{LE}_{\text{Japan}}$$

Result 2: Welfare Growth from 1980-2007

- 112 out of 125 countries have $g < \tilde{g}$ due to lower fertility in demographic transition ($e \uparrow$ and $n \downarrow$)
- 69 countries have $g > g_{\text{U.S.}}$ in Jones and Klenow, but only 38 countries have $\tilde{g} > \tilde{g}_{\text{U.S.}}$

Result 2: Welfare Growth of OECD Countries from 1980-2007

- 29 (out of 34) countries have $g > g_{\text{U.S.}}$, but **only 20 countries** have $\tilde{g} > \tilde{g}_{\text{U.S.}}$ after considering fertility and intergenerational altruism
- Cross-country convergence of welfare might have been **much slower** than previously thought
