

Asymmetric Fertility Elasticities

Sam Engle Chong Pang Anson Zhou

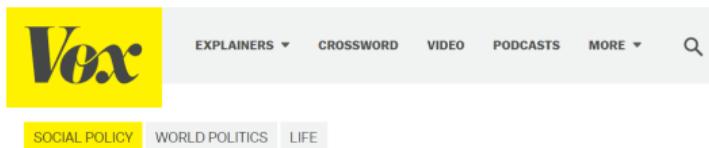

February 2025

The emergence of below-replacement fertility

- Major implications for the pension system, international relations, firm dynamics, economic growth...

Boosting fertility seems to be extremely difficult

The image shows the header of the Vox website. It features a yellow square logo with the word "Vox" in black lowercase letters. To the right of the logo is a grey navigation bar with the following menu items: EXPLAINERS ▾, CROSSWORD, VIDEO, PODCASTS, MORE ▾, and a magnifying glass icon for search. Below the main navigation, there are three smaller categories: SOCIAL POLICY (highlighted in yellow), WORLD POLITICS, and LIFE.

You can't even pay people to have more kids

These countries tried everything from cash to patriotic calls to duty to reverse drastically declining birth rates. It didn't work.

By Anna North | Nov 27, 2023, 8:00am EST

Worldwide Efforts to Reverse the Baby Shortage Are Falling Flat

Subsidized minivans, no income taxes: Countries have rolled out a range of benefits to encourage bigger families, with no luck.

34 40 min ago 9 min read

Reducing fertility seems to be easier

Many countries with low fertility problems now were reducing fertility not so long ago (e.g., China, Thailand, Singapore, Iran, . . .)

Did South Korea's Population Policy Work Too Well?

Romancing Singapore: When yesterday's success becomes today's challenge

Research Questions:

- Do fertility responds more to anti-fertility policies than pro-fertility ones?
- What could be the micro-foundation and what are the macro implications?

This paper

1. Motivating facts:
 - Stronger fertility responses to anti-fertility policy regimes and expenditures
 - Asymmetry challenges existing models ⇒ need a kink in fertility demand
2. A theory of fertility choice with reference-dependent preferences:
 - Explains the asymmetry and other important empirical regularities
 - Generates a “slippery slope” perspective: fertility could decline without changing economic fundamentals
 - Policy implications: precautionary motives to set a higher fertility rate target
3. Examine alternative explanations
 - (1) propagation, (2) technological asymmetry, (3) liquidity constraints

Literature

- Empirical evaluations of fertility policies
McElroy and Yang (2000), Liu and Raftery (2020), Schultz (2007), Milligan (2005), Laroque and Salanié (2014), Raute (2019), González and Trommlerová (2023)
- Structural models of fertility
Barro and Becker (1989), de la Croix and Doepke (2004), Córdoba and Ripoll (2019), Kim, Tertilt, and Yum (2024)
- Long-run fertility and population trajectories
Malthus (1872), Becker (1960), Easterlin (1968), Galor and Weil (2000), Feyrer et al. (2008), Lutz et al. (2007), Ibbetson (2019)

Motivating Facts

Data

- Fertility level and policy regime data from the United Nations
 - Policy regime dummy assigned by the UN Population Division since 1976 - lower, raise, maintain, no intervention
- Family planning funding from de Silva and Tenreyro (2017)
- Aggregate variables from PWT, WDI, Barro and Lee (2013): GDP per capita, urbanization, infant mortality, female labor force participation, education
⇒ panel regression for aggregate-level responses
- Individual-level data on fertility, education, and income from the World Value Survey (WVS) Database
⇒ cohort exposure design for individual-level responses

trend map

Panel regression

- We estimate the following specification

$$\begin{aligned}\Delta \text{TFR}_{it}/\text{TFR}_{it-1} = & \alpha + \beta_1 \text{Policy_Lower}_{it} + \beta_2 \text{Policy_Raise}_{it} \\ & + \beta_3 \text{Control}_{it} + \sigma_i + \eta_t + \epsilon\end{aligned}\quad (1)$$

- Control_{it} includes the level and growth rate of GDP per capita, education, urbanization, infant mortality, and female labor force participation
- Explanatory variables constructed by

$$\text{Policy_Lower}_{it} = \frac{1}{N} \sum_{T=t-N}^{t-1} \mathbb{I}(\text{Policy}_{iT} = \text{Lower})$$

$$\text{Policy_Raise}_{it} = \frac{1}{N} \sum_{T=t-N}^{t-1} \mathbb{I}(\text{Policy}_{iT} = \text{Raise})$$

Asymmetries at the aggregate level

Table 1: Population Policy and TFR

Dependent Variable Construction of Policy Variables	Δ Total Fertility Rate/Lagged Fertility Rate

compare

Cohort exposure design

- Using individual-level data, we estimate the following specification

$$\text{Child}_{icbt} = \alpha + \beta_1 \text{Policy_Lower}_{cb} + \beta_2 \text{Policy_Raise}_{cb} + \eta \text{Age}_i \times \text{Gender}_i + \gamma_{ct} + \delta_b + \epsilon \quad (2)$$

- Construct individual's exposure to policies in a 10-year fertile window around mean age of childbirth MAC_{cb} :

$$\text{Policy_Lower}_{cb} = \frac{1}{11} \sum_{t \in [b + \text{MAC}_{cb} - 5, b + \text{MAC}_{cb} + 5]} \mathbb{I}(\text{Policy}_{ct} = \text{Lower})$$

$$\text{Policy_Raise}_{cb} = \frac{1}{11} \sum_{t \in [b + \text{MAC}_{cb} - 5, b + \text{MAC}_{cb} + 5]} \mathbb{I}(\text{Policy}_{ct} = \text{Raise})$$

Asymmetries at the individual level

R ²	0.281	0.294	0.301	0.285	0.297	0.303	0.279	0.295	0.298

- Results mostly explained by changes in high-order births
- The degree of asymmetry increases in education/income

Intensive margin: -ve elasticity

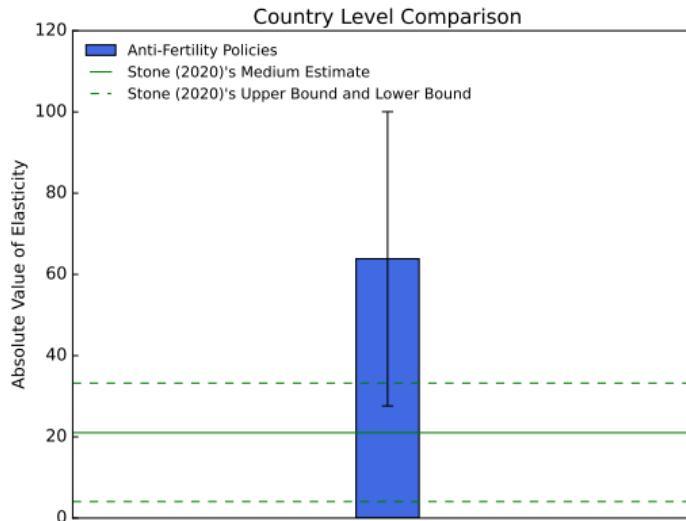

- Using data on family planning funding (de Silva and Tenreyro 2017)

Table 3: Elasticity Estimation for Anti-Fertility Policy

Dependent Variable	Δ Total Fertility Rate/ Lagged Total Fertility Rate	
Construction of Policy Variables	Average in the Last Five Years	
	(1)	(2)
Family planning funding-GDP Ratio	-60.72*** (22.65)	-79.71*** (25.29)
Country Fixed Effect	Yes	Yes
Year Fixed Effect	Yes	Yes
Control Variables	No	Yes
Observations	2754	2648
R^2	0.220	0.278

Asymmetries to expenditures

- Combine with harmonized estimates of pro-fertility policies (Stone 2020)

- The median estimate of pro-fertility elasticities lies outside of the 95% confidence interval of anti-fertility elasticities

Taking Stock

1. Aggregate fertility responds more to anti-fertility policy regimes and expenditure/GDP ratios
2. Individual fertility responds more to anti-fertility policy regimes during the fertile window + stronger asymmetry for individuals with higher SES

robust

Interpret together with three other findings in the literature:

1. Chatterjee and Vogl (2019): Fertility falls sharply in deep recessions but does not rise in rapid expansions, i.e., short-run asymmetries
2. González and Trommlerová (2023): When a pro-fertility policy was reversed, fertility fell below the initial level
3. Kearney et al. (2022): Puzzling decline in fertility w/o corresponding changes in economic fundamentals

panel Australia

Asymmetry challenges canonical models

- Most models of fertility choice typically look like

$$\max_{c,n,(e,\dots)} U(c, n, e, \dots) \quad \text{subject to} \quad c + \chi n + \dots = I$$

⇒ smooth aggregate Marshallian demand $n(\chi, I, \dots)$

- The smoothness result holds uniformly in a class of models

- Static and dynamic problems
- Altruistic and warm glow preferences
- Continuous and discrete fertility choices
- Representative and heterogeneous agents
- With and without quantity-quality trade-off or status competition

- Inconsistent w/ asymmetric elasticities $\underbrace{\frac{\partial n}{\partial \chi}}_+ > \underbrace{\frac{\partial n}{\partial \chi}}_-$, $\underbrace{\frac{\partial n}{\partial I}}_- > \underbrace{\frac{\partial n}{\partial I}}_+$

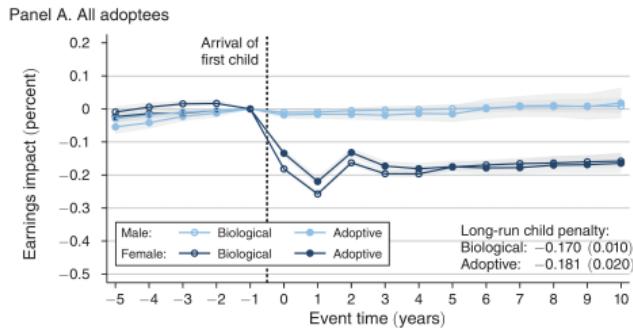

this paper

Chatterjee and Vogl (2019)

A new model of fertility choice

Why reference dependence?

- **Intuition:** having a child often implies sacrificing some other aspects of life upon which people could anchor their preferences

- WSJ: "In New Orleans, 42-year-old Beth Davis epitomizes some millennials' new views. 'I wouldn't mess up the dynamic in my life right now for anything, especially someone that is 100% dependent on me,' she says."

Model

- Conditional on reference r , solve

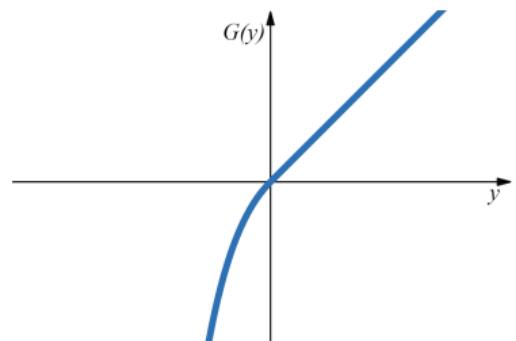

$$\max_{c,n} \quad \frac{1}{2}[u(c) + \beta u(n)] + \frac{1}{2}[G(u(c) - u(r)) + u(r)]$$

$$c + \chi n = I \quad u(n) = \frac{n^{1-\gamma} - 1}{1 - \gamma} \quad \gamma > 1$$

- c is interpreted as composite good
- Loss aversion when $\alpha > 0$

$$G(y) = \begin{cases} y & y \geq 0 \\ y - \alpha y^2 & y < 0 \end{cases}$$

- Consistency: $r = c$ in static model with RA

Result

- **Proposition 1:** Holding r unchanged, the optimal fertility response to an increase in χ is larger than the optimal response to a decrease in χ

$$\frac{\partial \log n^*}{\partial \log \chi} \Big|_{+, \alpha > 0} < \frac{\partial \log n^*}{\partial \log \chi} \Big|_{-, \alpha > 0} < 0 \quad (3)$$

which explains our empirical findings

- **Proposition 2:** Holding r unchanged, the optimal fertility response to a decrease in I is larger than the optimal response to a increase in I

$$\frac{\partial \log n^*}{\partial \log I} \Big|_{-, \alpha > 0} < \frac{\partial \log n^*}{\partial \log I} \Big|_{+, \alpha > 0} < 0 \quad (4)$$

which explains the finding in Chatterjee and Vogl (2019)

Dynamic extension

- In period t , fertile households takes r_t as given and choose $\{c_t(r_t), n_t(r_t)\}$
- Endogenous formation of the reference point

$$r_t = \phi \cdot r_{t-1} + (1 - \phi) \cdot c_{t-1} + \epsilon_t \quad \epsilon_t \sim \mathcal{N}(0, \sigma^2) \quad (5)$$

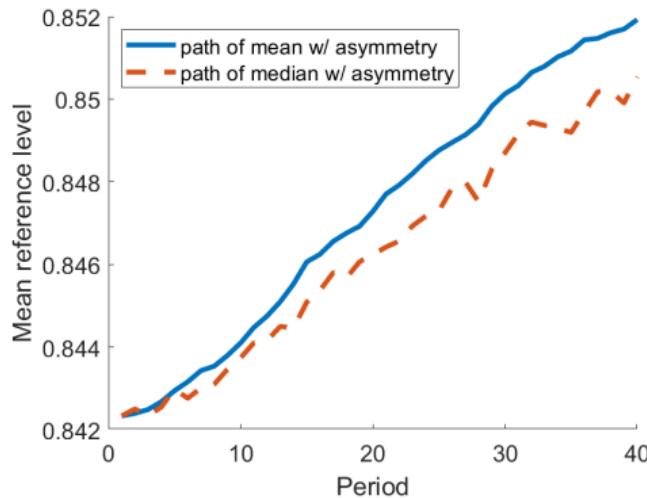

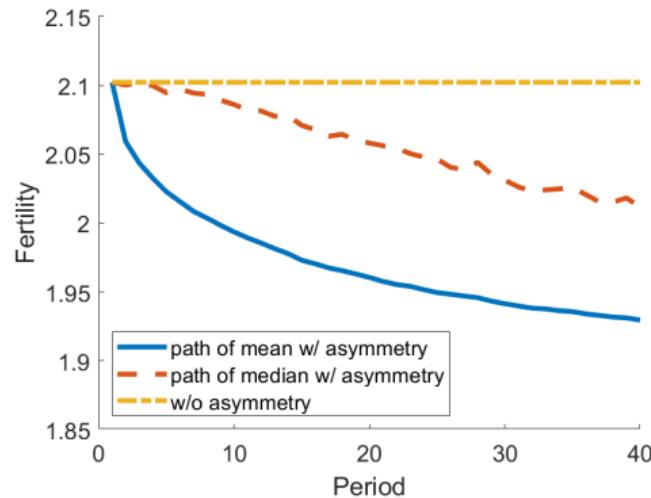

that formalizes the “relative status” in the Easterlin hypothesis

- ϕ is the persistence of past reference:
 - $\phi = 1$: random walk of r_t
 - $\phi = 0$: immediate updating $r_t = c_{t-1}$
- **The “slippery slope” perspective:** Starting from any consistent reference level $r_0 = c_0$, the expected fertility $\mathbb{E}_0(n_t)$ declines with time while the expected consumption $\mathbb{E}_0(c_t)$ and reference level $\mathbb{E}_0(r_t)$ rises with time.

Calibration

- Proof in the paper
- Illustration based on calibration:
 - Child costs $\chi = 0.075$ from Greenwood and Seshadri (2002)
 - Child preference $\beta = 34$ to generate $n_0 = 2.1$
 - Curvature $\gamma = 5.9$ and loss aversion $\alpha = 98$ to generate pro-fertility elasticity and the degree of asymmetry in the data
 - Updating parameters $\phi = 0.95$ and $\sigma = 0.01$ for annual frequency
- Simulate 10,000 paths for 40 years

The “slippery slope”

- Fertility rate slides without changes in the underlying economic fundamentals \Rightarrow different mechanism from existing theories
- Explains the puzzling fall in fertility since 2010 (Kearney et al. 2022)

Policy Implications

Government problem

- The policymaker faces social costs from population externalities

$$\mathcal{S}(n_t | \bar{n}) = \lambda \cdot (\log(n_t) - \log(\bar{n}))^2 \quad (6)$$

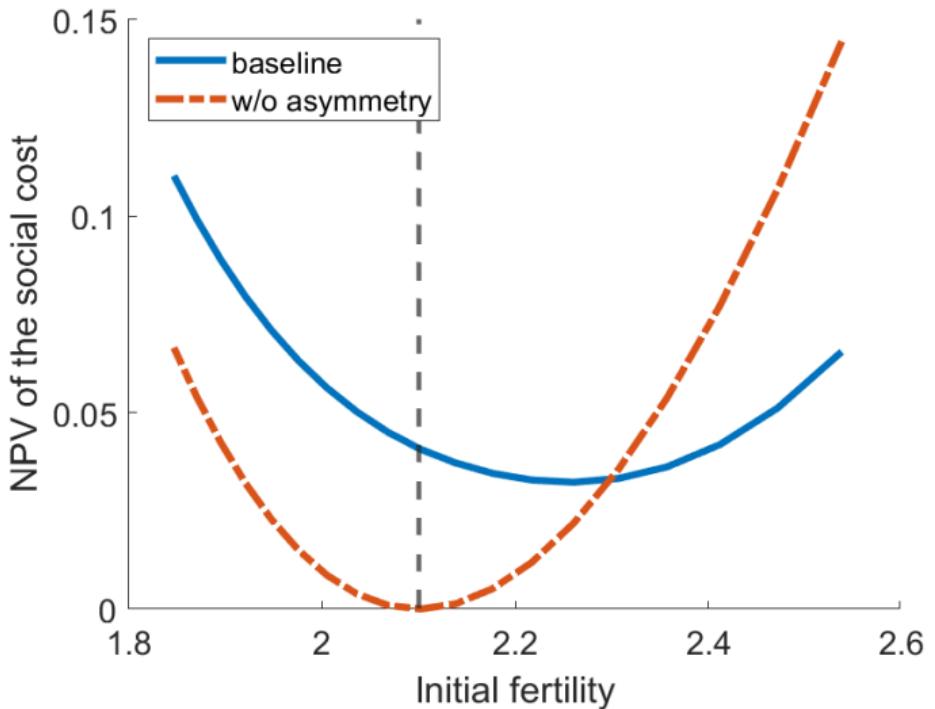

- Suppose the policymaker chooses n_0 (w/ consistent r_0) by permanently changing χ and solves

$$\min_{n_0} \quad \mathbb{E}_0 \sum_{t=0}^{\infty} \rho^t \mathcal{S}(n_t | \bar{n}) \quad (7)$$

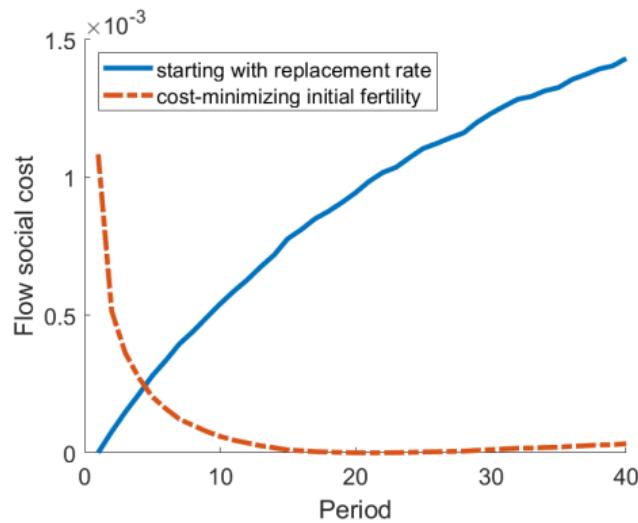

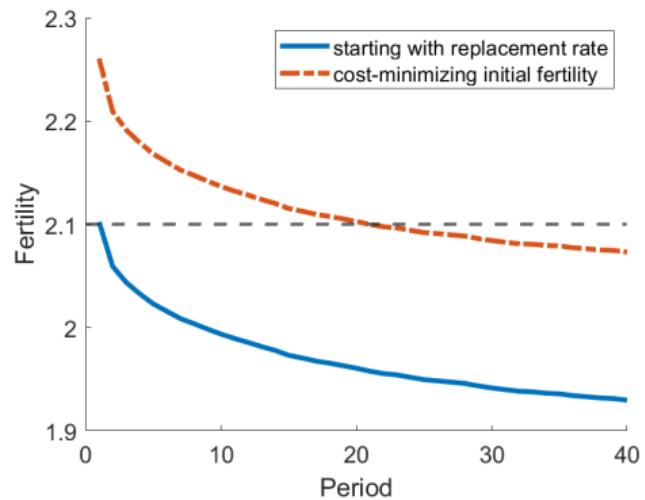

where n_t are optimizing choices by households

- Question:** What is the level of n_0 that minimizes the expected social cost?
- Set $\bar{n} = 2.1$, $\lambda = 0.2 \implies n_{\text{U.S. 2022}} = 1.62$ generates $\mathcal{S} = 0.62\%$ of GDP

Cost-minimizing initial fertility

Evolution of fertility and social cost

- When $\rho > 0$, there is an **intertemporal tradeoff** of social costs
- One can always find a path with $n_0 > \bar{n}$ that dominates $n_0 = \bar{n}$

Policy lessons

1. Precautionary motive of higher fertility rate target
2. To maintain n_0 , policy effort needs to increase in time
3. The cost-minimizing initial fertility level depends on the degree of asymmetry, the reference updating process, and the social discount factor

Alternatives

	Propagation Mechanism	Technological Asymmetry	Liquidity Constraints	Reference Dependence
Asymmetric responses w.r.t				
Fertility policies	✗	✓	✓	✓
Implementation and reversal	✗	✗	✗	✓
Income shocks	✗	✗	✓	✓
Puzzling fertility decline	✗	✗	✗	✓
Policy implications				
Precautionary high fertility	✗	✓	✗	✓
Rising pro-fertility effort	✗	✓	✗	✓

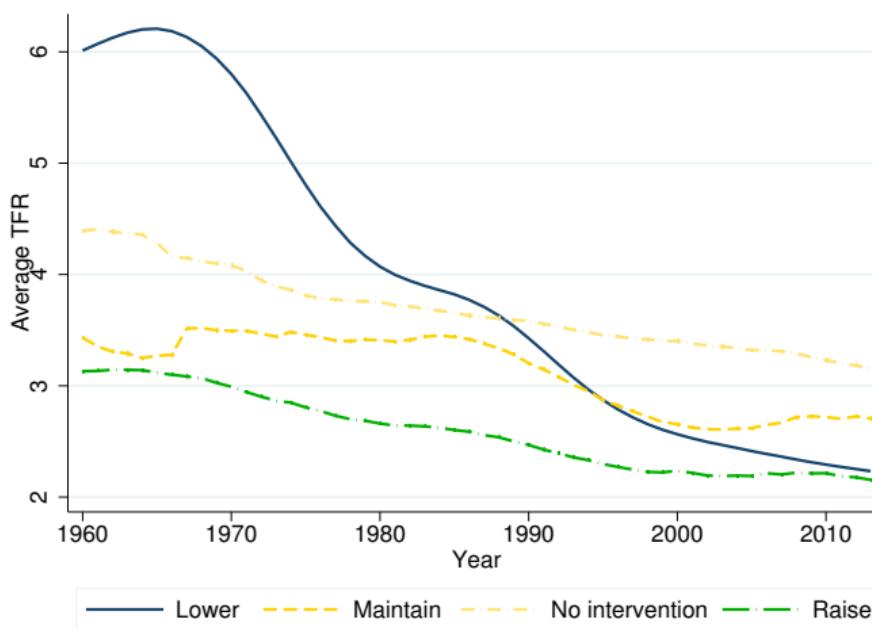

more

Conclusion

- Document asymmetric fertility responses to fertility policies
- Fertility choice under reference dependence explains this fact
- The theory also generates
 - Asymmetric responses to income shocks
 - Asymmetric responses to policy implementation and reversal
 - Fertility decline in the absence of changing fundamentals
- The “slippery slope” perspective offers new implications

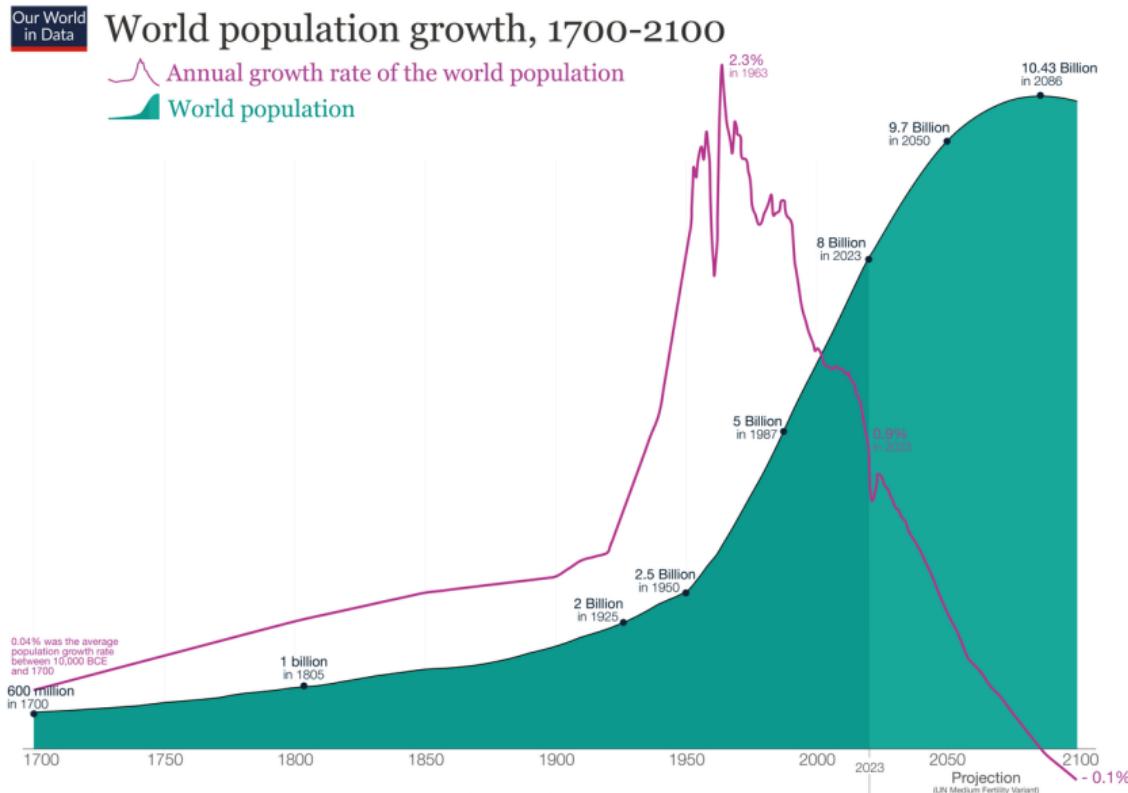

Appendix

Fertility trends by policy regime in 1976

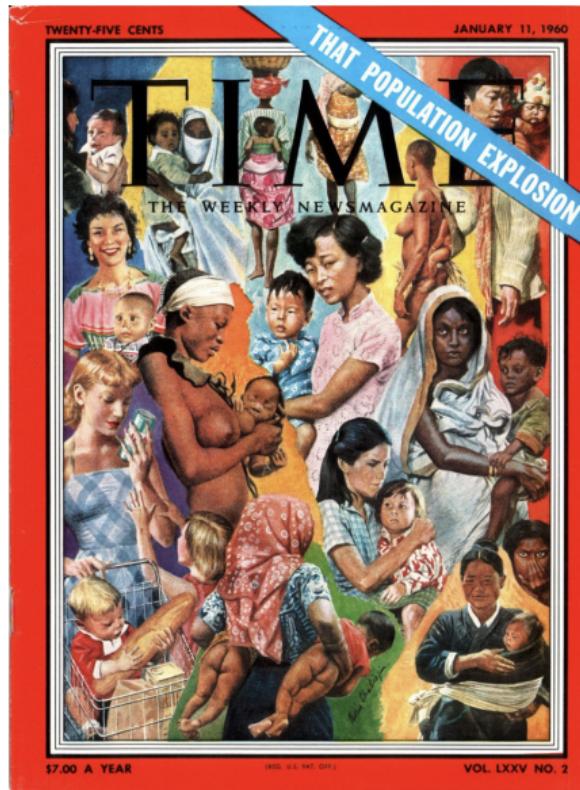

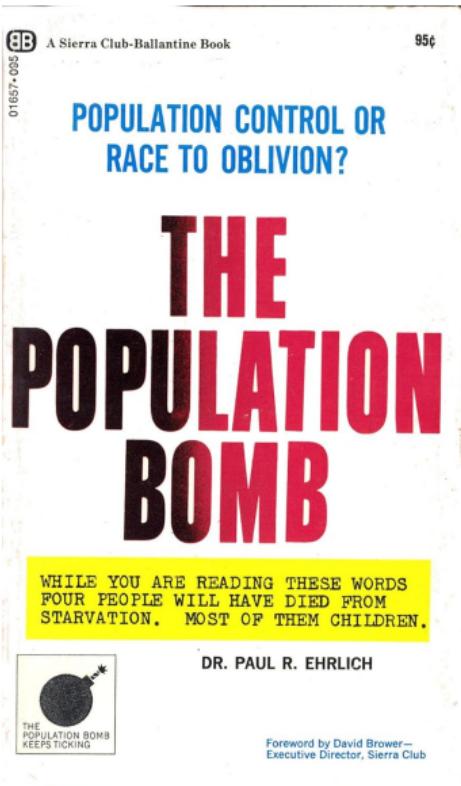

Fertility trends by policy regime in 1976

The specter of Malthus in the 1960s

The population bomb

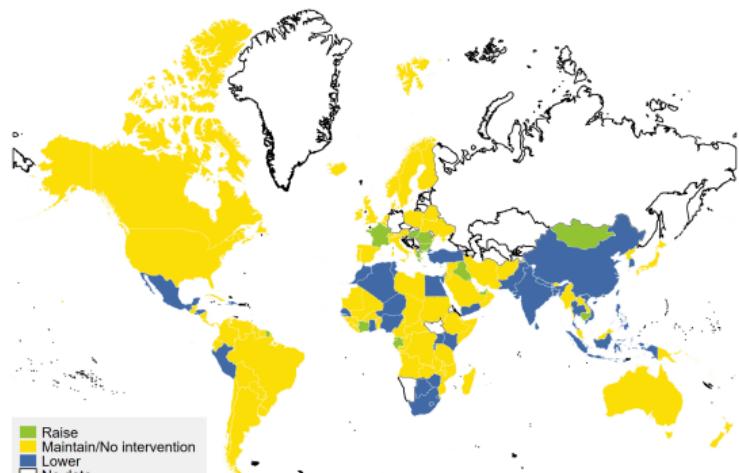

The global family planning movement

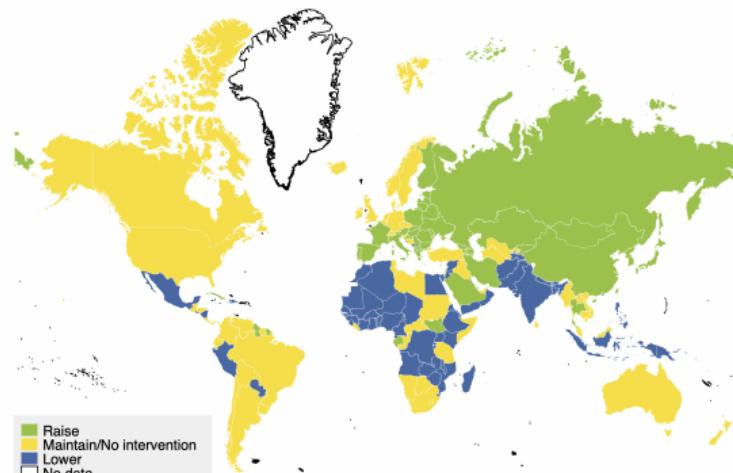

- Led by global organizations such as the United Nations, the World Bank, USAID, and Bill & Melinda Gates Foundation
- \$4.2 billion spent across low- & lower-middle-income countries in 2021
- Many country-specific policies (e.g., the one-child-policy in China)
- Gradually attaches more benefits to low fertility: economic development, health, gender equity, environment...
- Evidence that fertility policies played an important role in the rapid fertility decline (de Silva and Tenreyro 2020)

back

Asymmetries in policy effect on utility

- Loss aversion in preferences: asymmetric impacts on utilities
- Data: HILDA (Household, Income and Labour Dynamics) Survey from Australia
- Setup: unexpected changes in Australia's baby bonus policy
 1. \$2,000 increase in baby bonus for all births on July 1, 2004
 2. \$2,000 reduction in baby bonus for 2nd & higher-order births on July 1, 2013
- Empirical strategies:
 1. Regression discontinuity (RD) in time design
 2. Panel regression
- Fewer than 0.5% of annual births shifted in response to the policy (Gans and Leigh (2009))

Asymmetries in policy effect on utility: a RD in time design

- Evaluate the effect of 2004 reform:

$$\text{happiness}_i = \alpha + \beta \mathbb{1}(\text{last_birth}_i > \text{July 1}) + \gamma \text{control}_i + \epsilon \quad (9)$$

- Evaluate the effect of 2013 reform:

$$\begin{aligned} \text{happiness}_i = & \alpha + \beta \mathbb{1}(\text{last_birth}_i > \text{July 1}) \times \mathbb{1}(\text{Children_number}_i > 1) \\ & + \gamma \text{control}_i + \epsilon \end{aligned} \quad (10)$$

- Sample: respondents with at least one birth in the previous year
- Control variables: family size, children number, age, income, state \times socioeconomic status; all interacted with gender.

Baby Bonus Increase: Regression Discontinuity

back

Robustness

- Empirical finding is robust to
 1. Policy effects at different horizons
 2. Controlling for past fertility to mitigate reverse causality
 3. Split sample by initial fertility and GDP per capita
 4. Evaluate the cumulative contributions of policies to fertility changes for specific countries and compare with existing studies

back

Technological Reversibility

1. Propaganda: "It's better to make a family disappear than to make a second new birth appear" (China) & "have one for mum, one for dad and one for the country" (Australia) & "Do it for Denmark"
2. Family policies: childlessness tax (Soviet) & maternity capital (Russia)
3. Access to tech.: planned parenthood (global) & Decree 770 (Romania)
4. Reproductive coercion: forced sterilization (Bangladesh) & monthly gynecological exam w/ plant-level birth target (Romania)

Fertility policies have different combinations of cost-effectiveness and repugnancy. But each of them is **technologically feasible** in either direction

Control for past fertility

Table 12: Population Policy and TFR: Control Average TFR in the Last Five Years

Comparison with other existing studies

First-order condition

- The first-order condition of optimal consumption satisfies

$$u'(c) \cdot (1 + G'(u(c) - u(r))) = \frac{\beta}{\chi} \cdot u' \left(\frac{I - c}{\chi} \right)$$

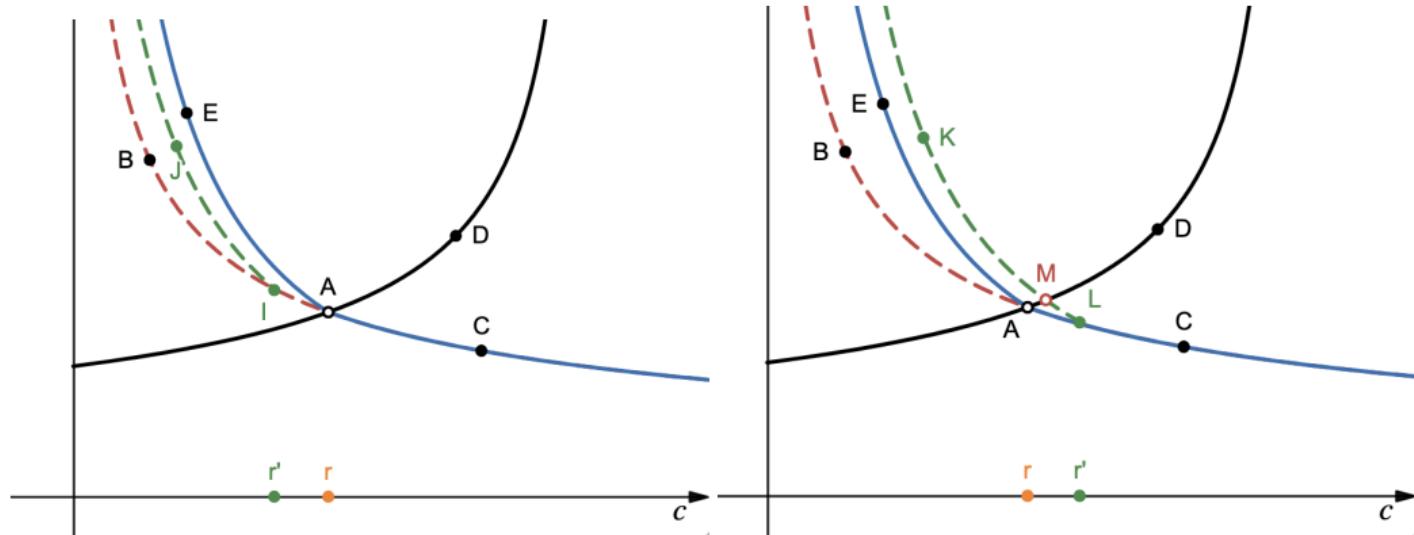

Asymmetry in χ

- Comparative static when χ falls (left) or rises (right)

back

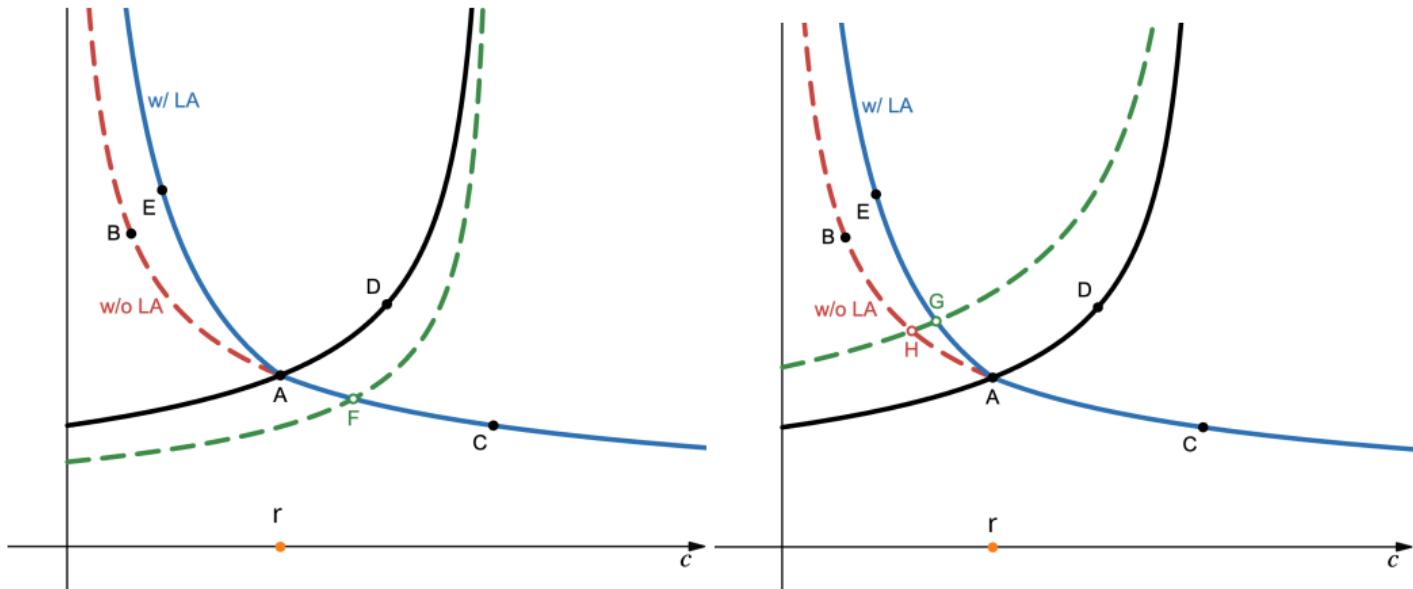

Asymmetry in r

- Comparative static when r falls (left) or rises (right)

back

Asymmetry in I

- Comparative static when I rises (left) or falls (right)
